Abstract. We show how automatic real-time facial expression recognition can be effectively used to estimate the level of difficulty, as perceived by an individual student, of a delivered lecture. We also show that facial expression data are predictive of an individual student's preferred rate of curriculum presentation at each moment in time. On a recorded video lecture viewing task, training on less than two minutes of recorded facial expression data, our system predicted the subjects' self-reported difficulty scores with mean accuracy of 42% (Pearson correlation) and the subjects' preferred viewing speed with mean accuracy of 29%. Our techniques are fully automatic and have potential applications for both intelligent tutoring systems and standard classroom environments. ¹

1 Introduction

This paper explores the utility of *facial expression* as a feedback signal from student to teacher. Previous work [2, 3] has investigated using facial expression for predicting the student's affective state. This paper investigates the usefulness of automatic expression recognition for two tasks: (1) measuring the student's perception of difficulty of a delivered lecture, and (2) determining a student's preferred viewing speed of lesson material. We conducted a pilot experiment in which subjects viewed a video lecture at an adjustable speed while their facial expressions were recognized automatically and recorded. Using the "difficulty" scores that the subjects report, the correlations between facial expression and difficulty, and between expression and preferred viewing speed, were assessed.

2 Experiment

We investigated whether students' facial expression can be used to estimate how difficult they find the lecture to be at each moment in time, as well as how fast they would prefer to receive the instruction. In our experiment, each of 8 human subjects watched a recorded video lecture 200 seconds (3 min 20 sec) in length. The lecture video consisted of 7 short video segments concatenated together about a disparate range of topics, including physics, philosophy, math, and teenage gossip. The experiment proceeded as follows:

¹ The full version of this paper is available at [1].

- 1. Watch the video lecture. The playback speed could be adjusted by the subject using the keyboard. Facial expression data of each human subject were recorded while they watched the video.
- 2. Take the quiz. The quiz consisted of 6 specific questions about the lecture.
- 3. Self-report on the difficulty. The lecture was re-played at a speed of 1.0. Subjects adjusted their rating of the video's difficulty on a scale of 1 to 10.

Facial expression data were analyzed and recorded automatically using the CERT system [4]. CERT outputs estimated intensities of facial "action units" (AUs) of face videos in real time. AUs can be regarded as the "phonemes" of facial expressions under the Facial Action Coding System [5], which is the standard framework for objectively coding nearly the entirety of human facial expression. CERT recognizes AUs 1, 2, 4, 5, 9, 10, 12, 14, 15, 17, 20, and 45 as well as Smile.

None of the subjects was aware of the purpose of the experiment or that expression data were recorded. Subjects were encouraged to view the video efficiently (by adjusting its speed) by a conspicuous automatic "shut-off" timer and a quiz. In actuality, the timer had no effect, and the quiz was not graded.

3 Analysis

Our experiment yielded three data series which we time-aligned:

- 1. **Difficulty**: The subjects' self-reported scores of how difficult they perceived the lecture at each moment in time.
- 2. Speed: The lecture speed at each moment as controlled by the user.
- 3. Expression: A set of real-valued expression channels output by CERT which estimate the intensity of 13 expression channels (12 AUs + Smile). The channels were smoothed using local quadratic regression.

We employed linear regression over the Expression channels to predict both Difficulty and Speed (see Figure 1 for an example). Separate regression models were trained for each subject. The average correlation (over all 8 subjects) of the Difficulty scores predicted by the regression model (training over all data) with the self-reported Difficulty scores was 75%, suggesting that facial expression contains a large amount of useful signal.

Subjects exhibited a wide variability of which expressions were correlated with Difficulty and Speed. The expression most consistently correlated was AU 45 ("blink"). The correlation was negative (subjects blinked less during more difficult lecture segments), which is consistent with evidence from experimental psychology that blink rate decreases when interest or mental load is high [6].

Generalization Performance: To assess the effectiveness of using facial expression to predict Difficulty and Speed values in a real intelligent tutoring system, we split the data series into disjoint training and validation sets (see [1] for details). Linear regression models over the Expression data series were trained on the training data to predict Difficulty and Speed for each human subject. Generalization performance was assessed by correlating predicted to self-reported Difficulty and Speed values over the validation data.

Fig. 1. Comparison of the self-reported Difficulty scores with the predicted Difficulty scores using linear regression over the facial expression channels for Subject #6. All data were used for training the regression model.

The average correlation across all subjects of predicted to self-reported Difficulty was 42%; the average correlation for Speed was 29%. Individual correlations were statistically significant for all but one subject. While these results show room for improvement, they already demonstrate the value of automatic real-time facial expression recognition in intelligent tutoring systems.

4 Conclusions

Our results have shown that automatic facial expression recognition is already a useful feedback signal for intelligent tutoring systems for two concrete tasks: perceived difficulty estimation, and preferred speed prediction. As expression recognition technology improves, its usefulness in ITS will continue to grow.
